

1953

LENGTH COMPOSITION OF CALIFORNIA COMMERCIAL CATCH OF PILCHARD, 1919-51

SPECIAL SCIENTIFIC REPORT: FISHERIES No. 105

**UNITED STATES DEPARTMENT OF THE INTERIOR
FISH AND WILDLIFE SERVICE**

Explanatory Note

The series embodies results of investigations, usually of restricted scope, intended to aid or direct management or utilization practices and as guides for administrative or legislative action. It is issued in limited quantities for the official use of Federal, State, or cooperating agencies and in processed form for economy and to avoid delay in publication.

United States Department of the Interior, Douglas McKay, Secretary

LENGTH COMPOSITION OF CALIFORNIA COMMERCIAL CATCH
OF PILCHARD, 1919 TO 1951

By

Margaret M. Calderwood

Special Scientific Report: Fisheries No. 105

Washington, D. C.
September 1953

Length Composition of California Commercial Catch
of Pilchard, 1919 to 1951

By

Margaret M. Calderwood

The data contained in this paper have been compiled from source files and are presented for use by fishery scientists for study of complex relationships which exist between age classes of a pelagic fishery. Knowledge of the relative size of each age class present in the population is required before changes can be determined. This knowledge is usually obtained by analysis of samples taken from the commercial catch. From this the history of each age class is developed and presented in the form of catch curves (Baranoff, 1918).

During the period of the California sardine fishery for which there are no data from tagging or from age determination, the length composition of the catches provides the only source of data from which catch curves may be derived.

Sardine length data have been shown by Silliman (1945) to be applicable to a period, before 1933, of lower fishing intensity for sardine when his estimate of total annual mortality amounted to 20 percent. Silliman also estimated the sources and degree of error in mortalities calculated from length composition as compared with certain populations having known mortality rates. He concluded (p. 195) that "at mortality rates of up to about 20 percent per year the error is negligible, but increases rapidly with increasing mortality rate above 20 percent. For this reason it is fortunate that other methods are available for the higher mortality rates prevailing under recent levels of exploitation."

For periods during which age data are available from spot samples only, or from incomplete collection, e.g., of otoliths (Mosher, in press), the age composition of small samples may be applied to the more representative samples of length composition of catches throughout a season in order to obtain an estimate of the age composition of the catch (Eckles, in press).

When age data for the catch are not available, length frequency data may further be useful in following changes in size and growth at various fishing intensities.

The following series of tables represents the length composition, so far as obtainable, of the commercial catch of sardines, Sardinops caerulea (Girard) 1854, in California from the 1919-20 through the 1950-51 season.

The length frequency tables are derived primarily from data collected by the California Department of Fish and Game. The tonnages include all records of sardine deliveries to shore plants, and during years when deliveries were made to floaters off San Francisco these are included. The catches of the San Francisco Floater fleet were compiled by the U. S. Fish and Wildlife Service. (Anonymous, 1948.)

The problem of sampling populations of migratory fish is not simple. Sette (1924, p. 70) reported results of analysis of data on length composition of catches taken during the first season of the sardine investigation, the winter of 1919-20, on which the sampling program in subsequent years largely is based. He summarizes (p. 90) "it may confidently be assumed that the choice of a sample from the boat load of sardines is truly random . . . the catch of sardines made by the cast of the net into or around a school of sardines is truly random except that schools of fish composed mainly of individuals under eighteen centimeters in length are avoided; but it may not be assumed that the assemblage of sardines in a school is truly random . . . With the sardines carrying on their own selection into schools, it cannot be hoped that validity of sampling may be determined on the basis of established statistical methods based on the random selection of individuals. This need not, however, preclude the investigation of the sardine by representative sampling."

Sette concluded (p. 96) "That to secure a representation sufficient to show the location of a distinct mode to within 10 percent of the probable movement of that mode within one year, a sampling of twice a week is necessary." He also concluded that this frequency of sampling was necessary "to determine the relative importance of fairly well defined and large size-groups within 10 percent error."

Thompson (1926) further emphasized errors of sampling and of selection, and forecast a future need for weighting the samples to the catch. He concluded (p. 188), "It is, from the point of view of the future program of great interest to define the most adequate and representative system of sampling. We have been unable to find any radical need for change from the present method except . . . the possibility of weighting each sample by the amount of the commercial catch it represents."

In the light of subsequent years of study of the fishery, it appears that the behavior of sardines, as reflected in their availability to the fishermen, and the variable contribution of different components of the stock, may magnify the difficulties of representative sampling.

The California Department of Fish and Game has carried on a program of sampling the commercial catch since 1919. The intensity of sampling has varied from year to year and from port to port. When sampling was first started at Monterey and San Pedro (in 1919), samples were taken daily from five boats. Later, semiweekly samples were obtained from five boats. A sample consisted of either 40 or 50 fish. In later years, samples have been taken from five boats daily, semiweekly, or weekly, all samples consisting of 50 fish.

Sardine sampling was extended to include San Francisco by the California Department of Fish and Game during the 1930-31 season. Owing to a lack of personnel, semiweekly sampling was not carried on at first, but whenever feasible 1,000 fish were measured in the middle of each lunar month. Regular sampling was started in 1935-36 and carried on by the California Department of Fish and Game until the 1938-39 season when catches were sampled by both California and the U. S. Fish and Wildlife Service. From that season to date all of the sampling in the San Francisco area has been done by the U. S. Fish and Wildlife Service. During the years of poor fishing in San Francisco and Monterey, samples were taken when fish were available.

The data are grouped in somewhat different time periods in the early records. Since it was difficult to secure monthly catch records for early years, the length frequencies of the samples were weighted to quarterly catch data from 1919 through 1925. Although during this period fishing continued throughout the year, only the fall, winter, and spring landings were used in calculating the season total (April, May, and June were omitted). This was done in order that the length composition of the catch might be comparable with later years when no regular fishing was carried on at this season.

From the 1926-27 through the 1937-38 seasons, catch records were available only by calendar month. All samples were weighted by calendar-month catches. From the 1938-39 season to date, all samples have been weighted to the lunar-month catches.

Because sampling was somewhat irregular in San Francisco from 1930-31 through 1937-38, the weighted frequencies of San Francisco and Monterey have been combined. During several months when fish were landed, no samples were taken in San Francisco. In these instances, the San Francisco catch was weighted to the Monterey samples.

Beginning in 1941-42, the average weight of the 50-fish sample from each boat was obtained. The number of fish caught each week was estimated from the total weight landed at each port divided by the average weight of fish sampled during that period. For seasons prior to 1941 estimates of the number of fish caught during each quarter, month, or lunar month were based on average length and weight data given by Clark (1928, pp. 37-38). Average weights of each size group were multiplied by the frequencies of the lengths in the monthly (or other) summaries to obtain the total weight of the samples. Total weight divided by the total number sampled yielded the average weight of fish taken during the period. The total catch for the period divided by the average weight provided the total number of fish landed. Totals are given in 100,000's of fish. In the few instances when the weighted total does not agree exactly with the catch in numbers of fish as recorded in other publications, the discrepancy is due to rounding of numbers.

During recent years when fishing was poor in Monterey and San Francisco, some of the northern plants had fish trucked north from southern California. All fish taken south of Point Conception were included with the San Pedro catch totals, even though they were delivered to another port. The practice of trucking fish north was initiated in the 1946-47 season.

SOURCE OF DATA

SAN FRANCISCO LENGTH FREQUENCIES:

1919-20 through 1929-30: No records were available, no samples taken.

1930-31 through 1937-38: (Combined with Monterey) Frequencies were tabulated by and weighted to total landing for each calendar month, separately for each port and then combined. When fish were landed and no samples taken, length frequencies were used for corresponding months in Monterey and weighted to the San Francisco catch. This was done in the following instances:

1930-31 - Dec., Feb.
1931-32 - Aug., Feb.
1932-33 - Aug., Sept., Nov., Dec., Jan., Feb.
1933-34 - Aug., Oct., Dec., Jan., Feb.
1934-35 - Aug., Oct., Feb.
1935-36 - Aug., Feb.
1936-37 - Aug.
1937-38 - Feb.

1938-39 through 1950-51: Frequencies were tabulated by and weighted to lunar-month catch. (There was no fishery in San Francisco during either the 1947-48 or 1948-49 seasons.)

SAN FRANCISCO CATCH DATA:

1930-31 through 1937-38: Catch in tons by calendar months were taken from Bureau of Commercial Fisheries (1929-1937) and Bureau of Marine Fisheries (1940).

1938-39 through 1940-41: Catch in tons by lunar month were taken from California Sardine Products Institute records and unpublished records of the San Francisco floater fleet.

1941-42 through 1950-51: Catch in thousands of fish per lunar month were taken from Felin and Phillips (1948); Mosher, Felin, and Phillips (1949); Felin, Phillips, and Daugherty (1949); and Felin, Daugherty, and Pinkas (1950 and 1951).

MONTEREY LENGTH FREQUENCIES:

1919-20 through 1925-26: Frequencies were tabulated by and weighted to quarters by combining calendar-month frequencies.

1926-27 through 1937-38: Frequencies were tabulated by and weighted to calendar-month catch. (Combined with San Francisco for period 1930-31 through 1937-38)

1938-39 through 1950-51: Frequencies were tabulated by and weighted to lunar-month catch.

MONTEREY CATCH DATA:

1919-20 through 1925-26: Catch in tons by calendar month were taken from California Fish and Game (1920-26).

1926-27 through 1937-38: Catch in tons by calendar month were taken from Bureau of Commercial Fisheries (1929-37) and Bureau of Marine Fisheries (1940).

1938-39 through 1950-51: Same as San Francisco.

SAN PEDRO LENGTH FREQUENCIES:

1919-20 through 1925-26: By quarters; same as Monterey.

1926-27 through 1937-38: By calendar months; same as Monterey.

1938-39 through 1950-51: By lunar months; same as Monterey.

SAN PEDRO CATCH DATA:

1919-20 through 1925-26: By quarters; same as Monterey.

1926-27 through 1937-38: By calendar months; same as Monterey.

1938-39 through 1950-51: By lunar months; same as San Francisco.

I wish to thank O. E. Sette for his many suggestions and his help in compiling these data and Ralph P. Silliman for much of the preliminary work. Dr. Frances N. Clark and others on the staff of the California State Fisheries Laboratory have been exceedingly cooperative in making the original data available. I also am grateful to Dr. E. H. Ahlstrom and John C. Marr for their assistance in the final preparation for publication.

Table 1

CALENDAR DATES OF LUNAR MONTHS FOR SEASONS 1938-39 THROUGH 1950-51

	Lunar Month No.	Designation	Dates
Season 1938-39:	232	"July"	July 12-Aug. 10
	233	"August"	Aug. 11-Sept. 8
	234	"September"	Sept. 9-Oct. 8
